

Winning Space Race with Data Science

Dhery Setiawan 08/04/2023

Outline

- Executive Summary
- Introduction
- Methodology
- Results
- Conclusion
- Appendix

Executive Summary

- We gathered information by scraping the SpaceX Wikipedia page and using the open SpaceX API. 'Class', a newly created labels column, is used to identify all successful landings. We used dashboards, folium maps, SQL, visualization, and EDA (Exploratory Data Analysis). Then, we gathered the pertinent columns for our pieces. Then, using One Hot Encoding, we converted all of the categorical variables to binary. We utilized GridSearchCV to identify the ideal parameters for our machine learning models using standardized data. We then displayed the accuracy rating for each model.
- We implemented the Logistic Regression, Support Vector Machine (SVM), Decision Tree Classifier, and K Nearest Neighbors machine learning models. All yielded data that were comparable and had an accuracy percentage of about 83.33%. Successful landings were anticipated by all models. It is obvious that additional data is necessary for improved model selection and accuracy.

Introduction

• On its website, Space X promotes Falcon 9 rocket launches for 62 million dollars, other suppliers charge upwards of 165 million dollars for each launch. A large portion of the savings is due to Space X's ability to reuse the first stage. So, if we can figure out whether the first stage will land, we can figure out how much a launch will cost. If another business wishes to submit a proposal for a rocket launch against space X, they can use this information. The project's objective is to build a pipeline for machine learning that can forecast if the initial stage will land successfully.

Methodology

Executive Summary

- Data collection methodology:
 - Data was collected using SpaceX API and web scraping from Wikipedia.
- Perform data wrangling
 - One-hot encoding was applied to categorical features
- Perform exploratory data analysis (EDA) using visualization and SQL
- Perform interactive visual analytics using Folium and Plotly Dash
- Perform predictive analysis using classification models
 - How to build, tune, evaluate classification models

Data Collection

The information was gathered in numerous ways.

- Utilizing a get call to the SpaceX API, data was gathered.
- Next, we used the .json() function call to decode the response's content as JSON and the .json_normalize() method to convert it to a pandas dataframe.
- The data was then cleansed, missing values were checked for, and filled in as appropriate.
- Additionally, using BeautifulSoup, we scraped Wikipedia for information on Falcon 9 launch statistics.
- The goal was to extract the launch records as an HTML table, parse it, and then transform it into a pandas dataframe for later analysis.

Data Collection - SpaceX API

Get request for rocket launch data using API

Use json_normalize method to convert json result to datafíame

Preprocessing the data

```
spacex_url="https://api.spacexdata.com/v4/launches/past"

response = requests.get(spacex_url)
```

Use json_normalize meethod to convert the json result into a dataframe
data = pd.json_normalize(response.json())

```
# Lets take a subset of our dataframe keeping only the features we want a
nd the flight number, and date utc.
data = data[['rocket', 'payloads', 'launchpad', 'cores', 'flight number',
'date utc']]
# We will remove rows with multiple cores because those are falcon rocket
s with 2 extra rocket boosters and rows that have multiple payloads in a
single rocket.
data = data[data['cores'].map(len)==1]
data = data[data['payloads'].map(len)==1]
# Since payloads and cores are lists of size 1 we will also extract the s
ingle value in the list and replace the feature.
data['cores'] = data['cores'].map(lambda x : x[0])
data['payloads'] = data['payloads'].map(lambda x : x[0])
# We also want to convert the date utc to a datetime datatype and then ex
tracting the date leaving the time
data['date'] = pd.to datetime(data['date utc']).dt.date
# Using the date we will restrict the dates of the launches
data = data[data['date'] <= datetime.date(2020, 11, 13)]
```

Data Collection - Scraping

Request the Falcon9 Launch Wiki page from url

Create a BeautifulSoup from the HTML response

Extract all column/variable names from the HTML header

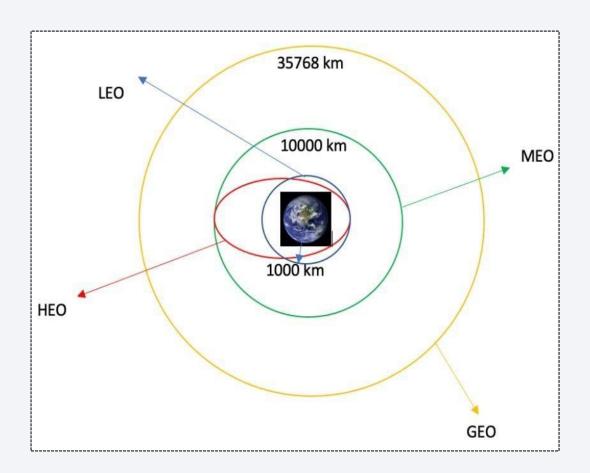

```
# use requests.get() method with the provided static_url
# assign the response to a object
data = requests.get(static_url).text
```

```
# Use BeautifulSoup() to create a BeautifulSoup object from a response te
xt content
soup = BeautifulSoup(data, 'html.parser')
```

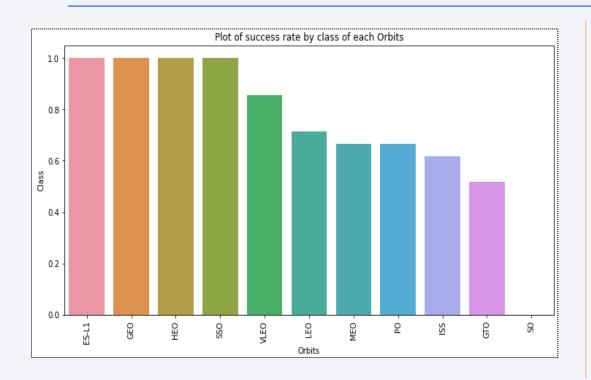

```
extracted row = 0
#Extract each table
for table_number, table in enumerate(soup.find_all('table', "wikitable plainrowheaders collapsible")):
  # get table row
   for rows in table.find all("tr"):
        #check to see if first table heading is as number corresponding to Launch a number
        if rows.th:
           if rows.th.string:
                flight_number=rows.th.string.strip()
                flag=flight number.isdigit()
        else:
            flag=False
        #get table element
        row=rows.find_all('td')
        #if it is number save cells in a dictonary
        if flag:
            extracted_row += 1
            # Flight Number value
           launch dict['Flight No.'].append(flight number)
            # TODO: Append the flight_number into Launch_dict with key `Flight No.`
            #print(flight_number)
           print(flight_number)
           datatimelist=date time(row[0])
           # Date value
            # TODO: Append the date into Launch dict with key `Date`
           date = datatimelist[0].strip('.')
            launch dict['Date'].append(date)
           print(date)
            #print(date)
```

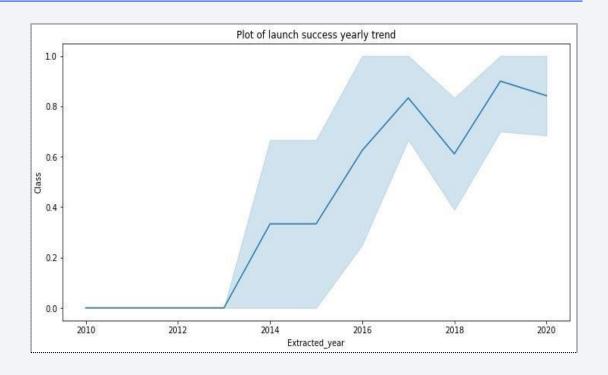

Data Wrangling

- Exploratory data analysis was done to establish the training labels.
- We determined the number of launches at each location as well as the frequency and number of orbits.
- We used the outcome column to build the landing outcome label and saved the data to CSV.

EDA with Data Visualization

We explored the data by visualizing the relationship between flight number and launch Site, payload and launch site, success rate of each orbit type, flight number and orbit type, the launch success yearly trend

EDA with SQL

- Displaying the names of the launch sites.
- Displaying 5 records where launch sites begin with the string 'CCA'.
- Displaying the total payload mass carried by booster launched by NASA (CRS).
- Displaying the average payload mass carried by booster version F9 v1.1.
- Listing the date when the first successful landing outcome in ground pad was achieved.
- Listing the names of the boosters which have success in drone ship and have payload mass greater than 4000 but less than 6000.
- Listing the total number of successful and failure mission outcomes.
- Listing the names of the booster_versions which have carried the maximum payload mass.
- Listing the failed landing_outcomes in drone ship, their booster versions, and launch sites names for in year 2015.
- Rank the count of landing outcomes or success between the date 2010-06-04 and 2017-03-20, in descending order.

Build an Interactive Map with Folium

- To use an interactive map to show the launch data. We took the scope and longitude organizes at each send off site and added a circle marker around each send off site with a mark of the name of the send off site.
- In MarkerCluster(), we then assigned the dataframe launch_outcomes(failure, success) to classes 0 and 1, respectively, with red and green markers on the map.
- The launch sites' distances from various landmarks were then calculated using the Haversine's formula to answer the following questions: How close are the launch sites to highways, coastlines, and railways? And How close the launch sites with nearby cities?

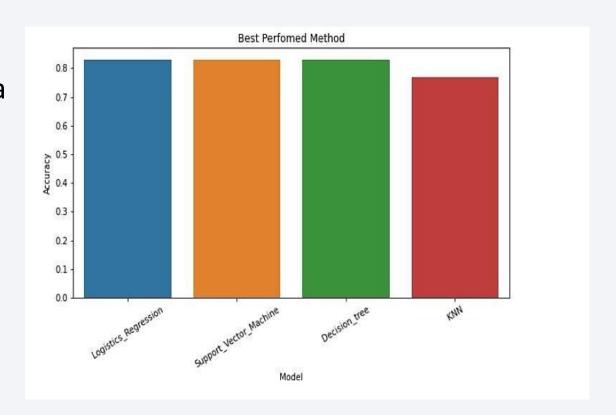

Build a Dashboard with Plotly Dash

- We built an interactive dashboard with Plotly dash which allowing the user to play around with the data as they need.
- We plotted pie charts showing the total launches by a certain sites.
- We then plotted scatter graph showing the relationship with Outcome and Payload Mass (Kg) for the different booster version

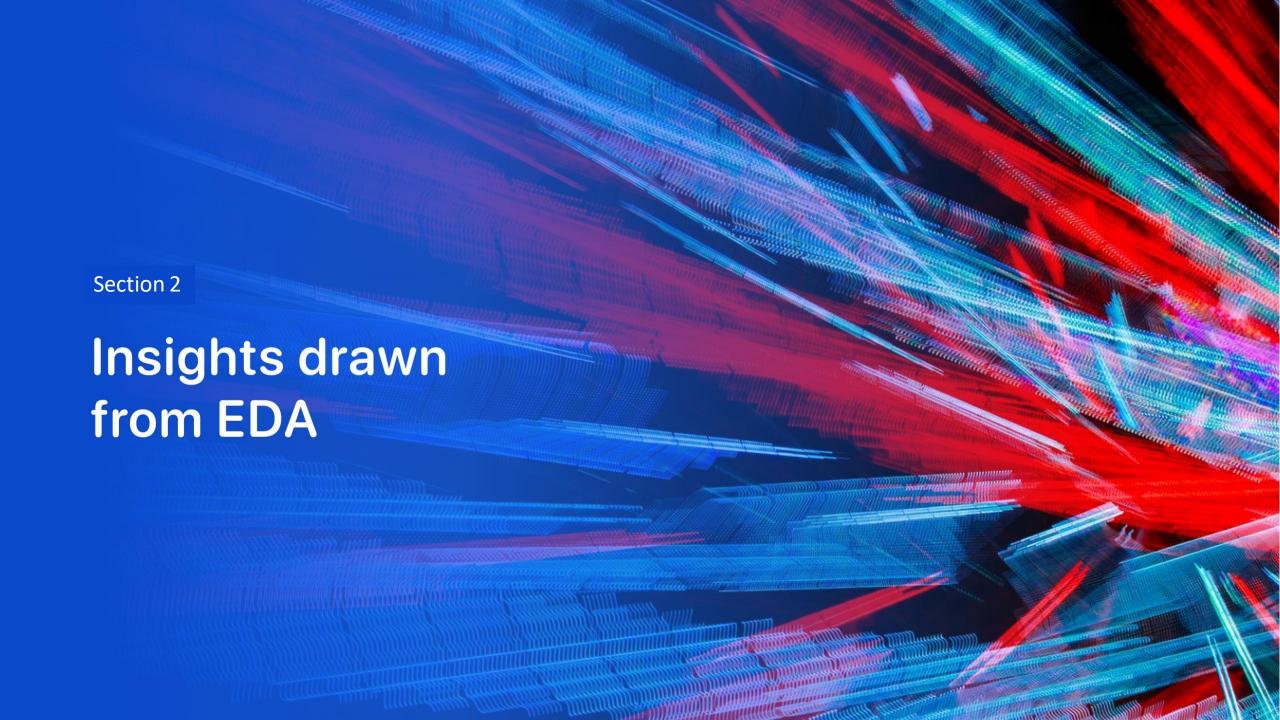

Predictive Analysis (Classification)

- We loaded the data using numpy and pandas, transformed the data, split our data into training and testing.
- We built different machine learning models and tune different hyperparameters using GridSearchCV.
- We used accuracy as the metric for our model, improved the model using feature engineering and algorithm tuning.
- We found the best performing classification model

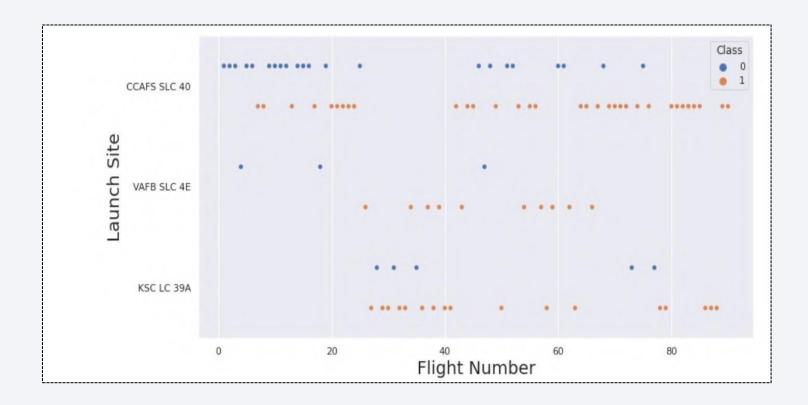

Results

- Exploratory data analysis results
- Interactive analytics demo in screenshots
- Predictive analysis results

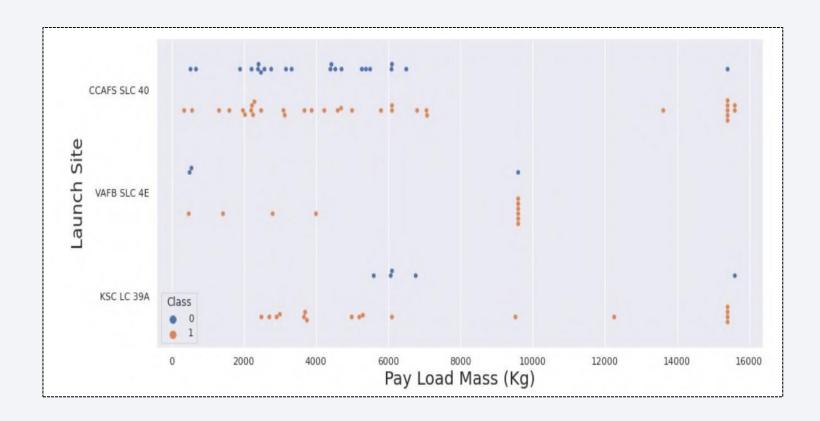

Flight Number vs. Launch Site

 As flight numbers were increasing, the success rate also increased

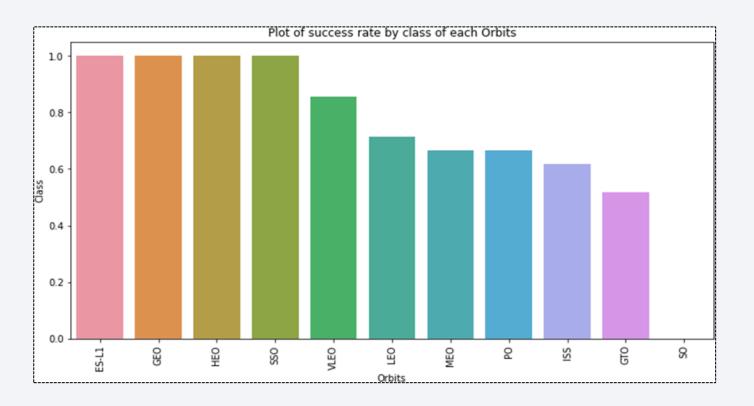

Payload vs. Launch Site

 The greater payload mass for launch site CCAFS SLC 40 the higher success rate for the rocket

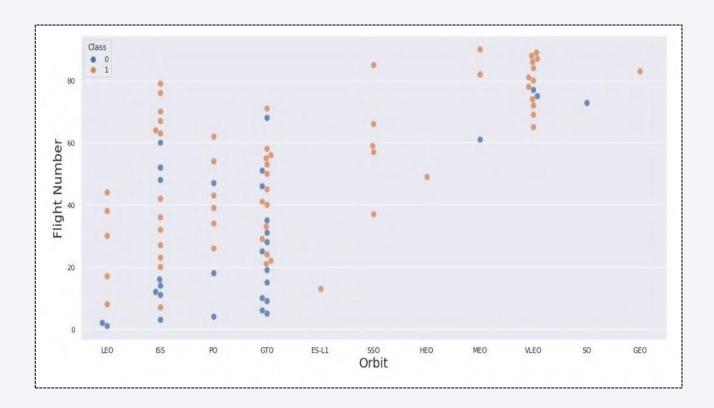

Success Rate vs. Orbit Type

• From the plot, we can see that ES-L1, GEO, HEO, SSO, VLEO had the most successrate.

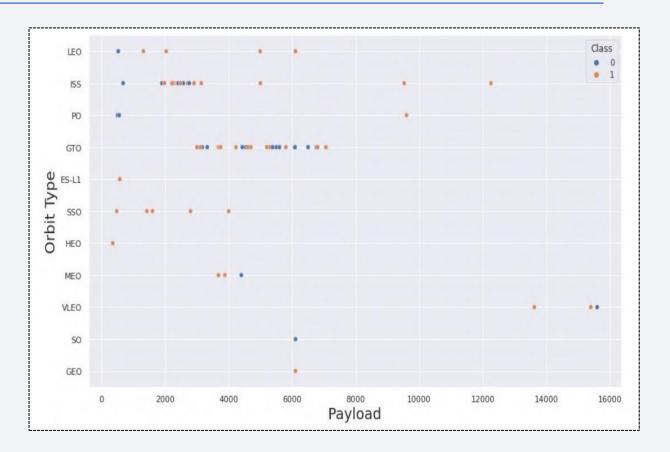

Flight Number vs. Orbit Type

 The plot below shows the Flight Number vs. Orbit type. We observe that in the LEO orbit, success is related to the number of flights whereas in the GTO orbit, there is no relationship between flight number and the orbit.

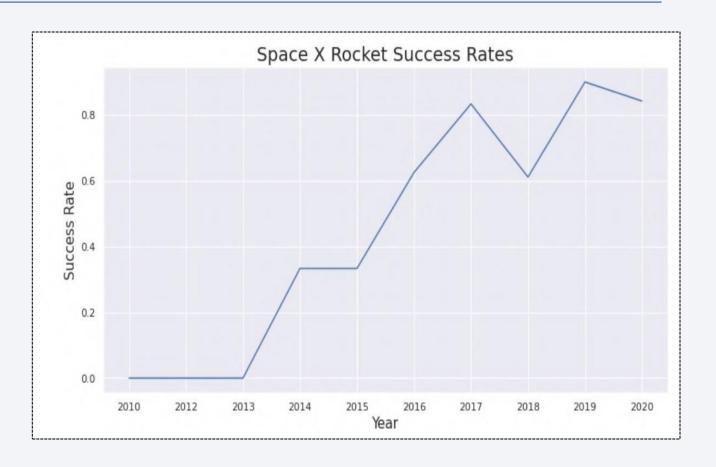

Payload vs. Orbit Type

 Heavier payload has positive impact on LEO, ISS and PO orbit. However, it has negative impact on MEO and VLEO orbit.

Launch Success Yearly Trend

 This figures clearly depicted and increasing trend from the year 2013 until 2020.

All Launch Site Names

Launch Site Names Begin with 'CCA'

n [11]:	Lo	FRO WHE LIM	ECT * M SpaceX RE Launc IT 5	hSite LIKE 'CC

2015 Launch Records

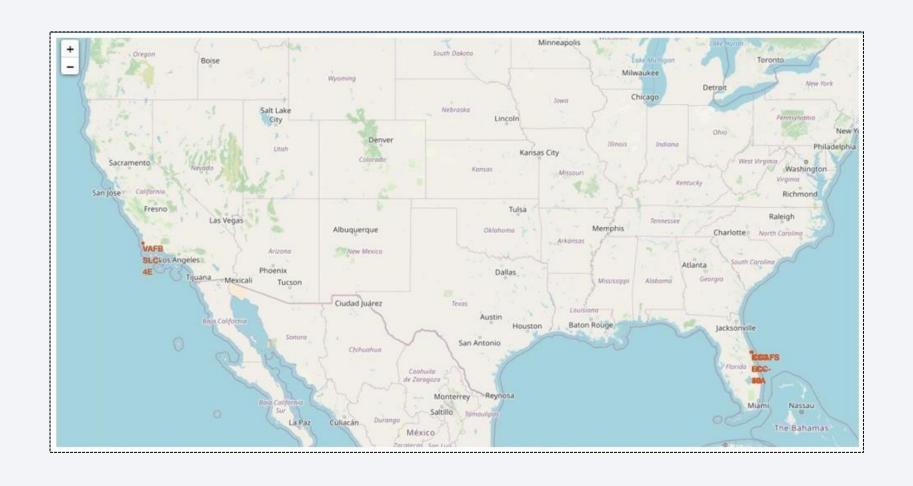

Rank Landing Outcomes Between 2010-06-04 and 2017-03-20

Location of all the Launch Sites

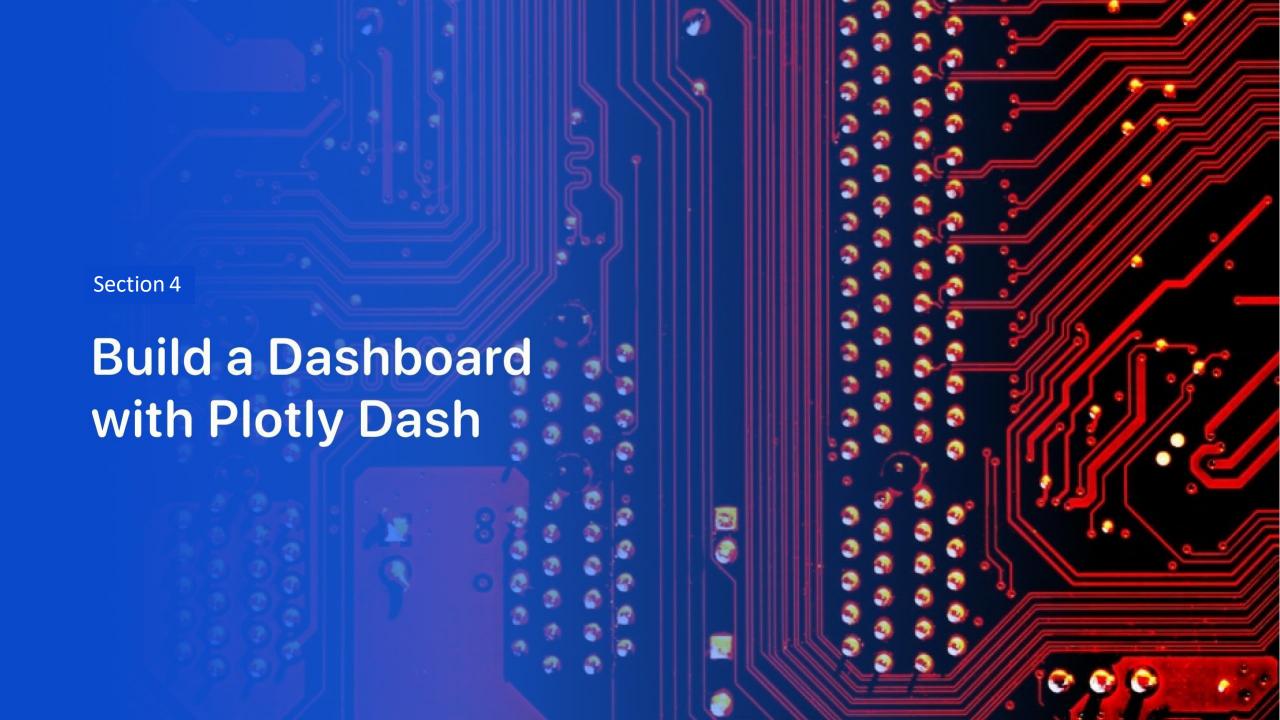

Launch Sites Outcome

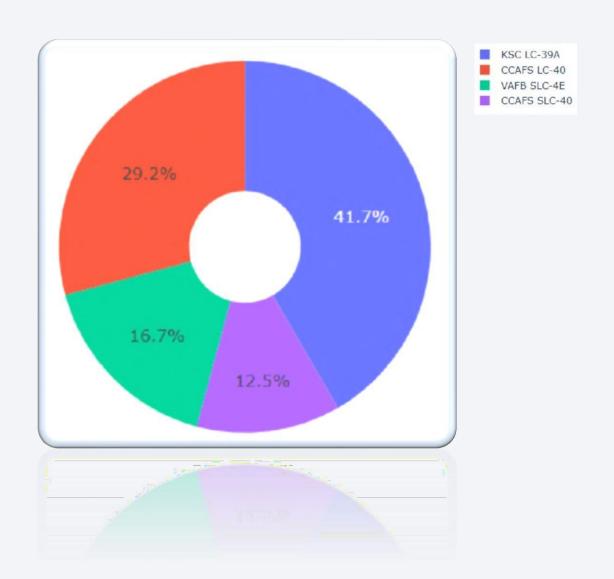

Launch Site Vicinity

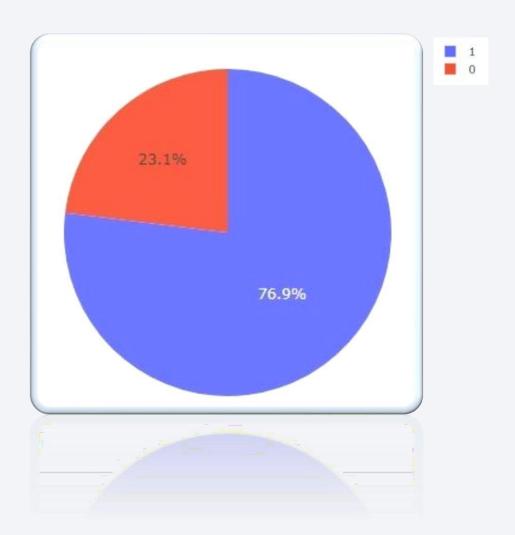

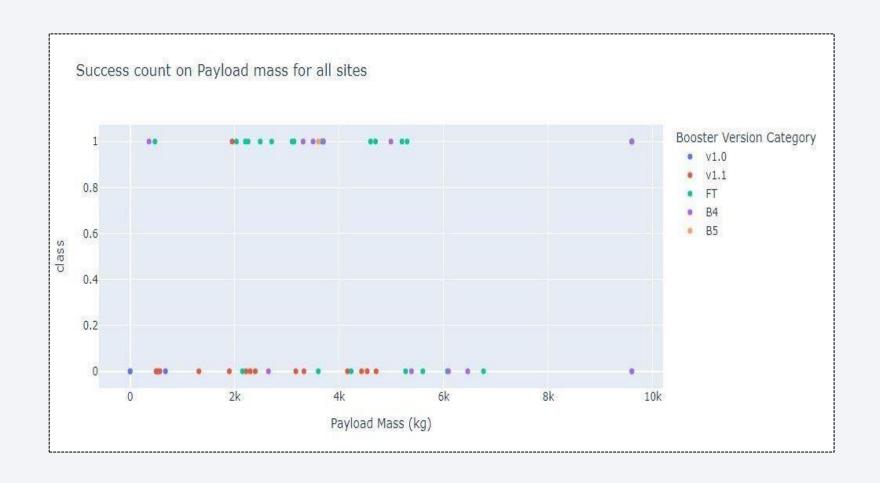

The success percentage by each sites

The highest launch-success ratio: KSCLC-39A

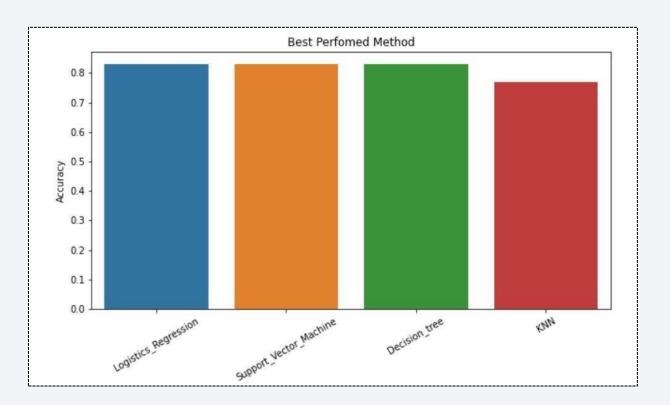

Payload vs Launch outcome

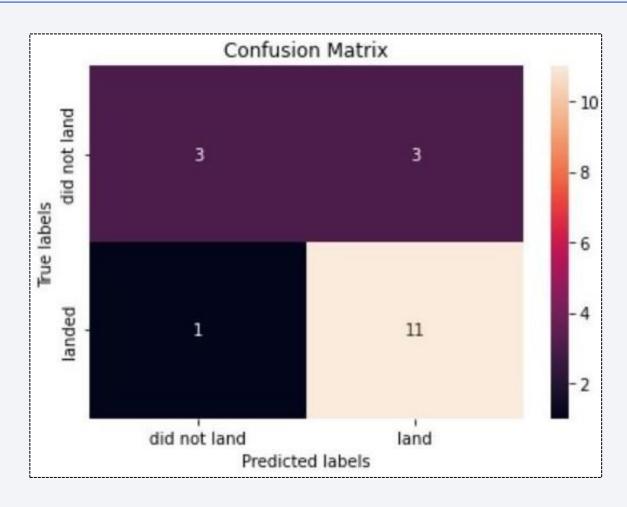

Classification Accuracy

 Logistic Regression, SVM and Decision Tree were the best models with accuracy around 0.83

Confusion Matrix

Conclusions

- Launch site with highest score was KSC LC-39A
- The payload of 0 to 5000 Kg was more diverse than 6000 to 10000 kg
- Logistic Regression, SVM and Decision Tree were very similar with accuracy around 0.83
